Question: 1

In which two ways is the status of a service calculated? Select TWO.

- A. By the severity of messages that reference the service ID of the service
- B. By the severity of messages that reference the service's subordinates
- C. By the status of subordinate services that are propagated
- D. By the status of superordinate services while the propagation rule is NOT ignored

Answer: A, C

Question: 2

What occurs when a message is owned by one of the operators?

- A. The related service state is recalculated and the message is no longer used for the calculation.
- B. The related service state is NOT recalculated.
- C. The related service state is set to 'Normal'
- D. The related service state is NOT recalculated only if it is configured to use multi-threshold calculation rules

Answer: B

Question: 3

What is the correct definition of a status calculation rule?

- A. Each relation between two services contains a rule regarding how the subordinate status is seen by the superordinate service. Subordinate services can be less important or more important for the superordinate service.
- B. If the calculation rule additionally defines "set to critical", the status of the service will always be critical.
- C. Each service defines how it determines its own status from the various status propagated by its subordinates, and messages that apply to the service itself.
- D. The status of the lowest level services is equal to the last received active message for that service.

Answer: C

Question: 4

How is the status of nodes determined? Select TWO.

- A. The status of a node is based on the most severe message for this node.
- B. If only messages of severity "unknown" and "normal" exist, the corresponding node will have status "normal".
- C. If only messages of severity "unknown" exist, the node's status will be unknown.
- D. The status of a node is based on the last message received for this node.
